

# Linux Command Line Practical Task

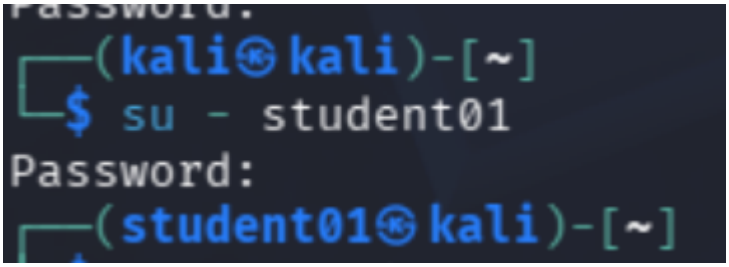

## Objective

Demonstrate your understanding of basic Linux commands by completing the following tasks **as a newly created user** in **Kali Linux**.

### STEP 1: Create and Switch to a New User

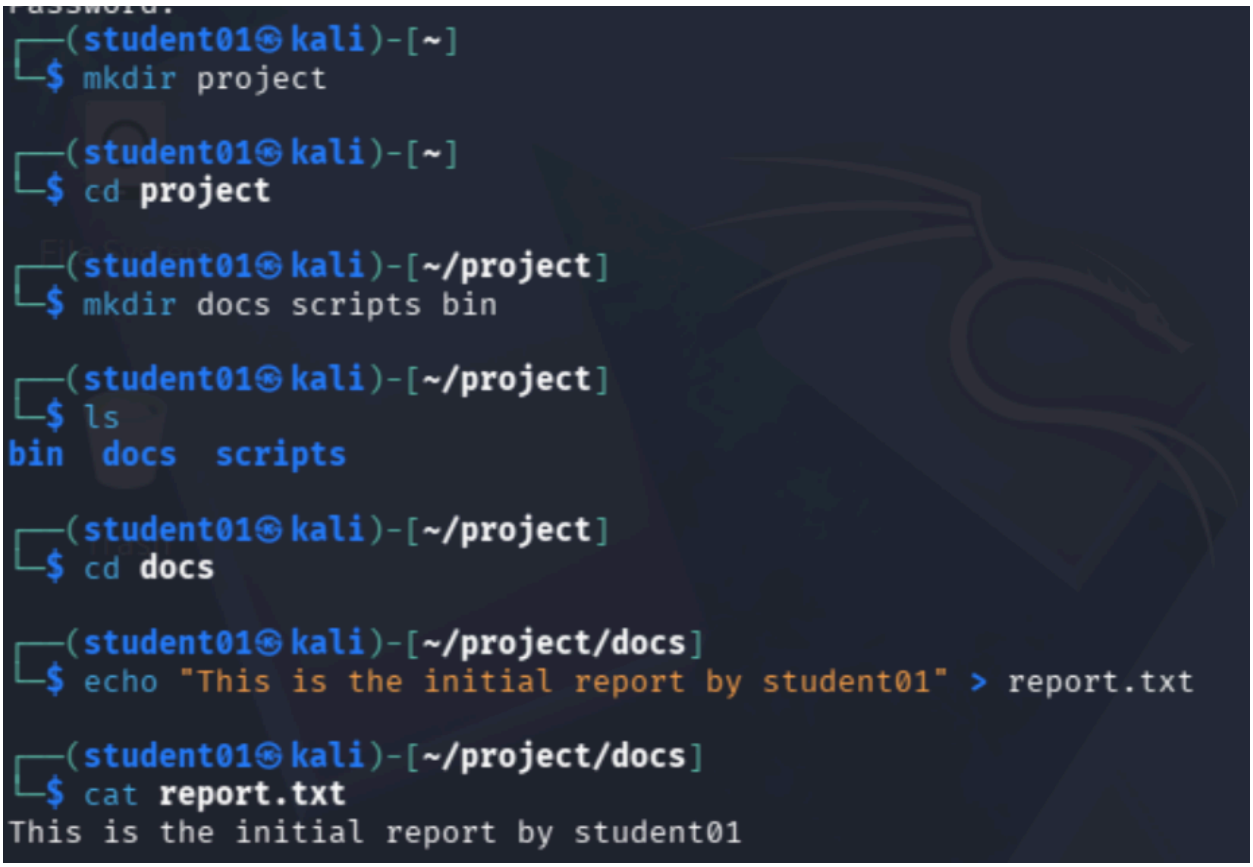

1. Open the terminal.
2. Create a new user called: `student01`
3. Set a password for the user.
4. Add the user to the sudo group (if required).
5. Switch to the new user using the `su` or `login` command.
6. Confirm you're logged in as `student01` by running: `whoami`

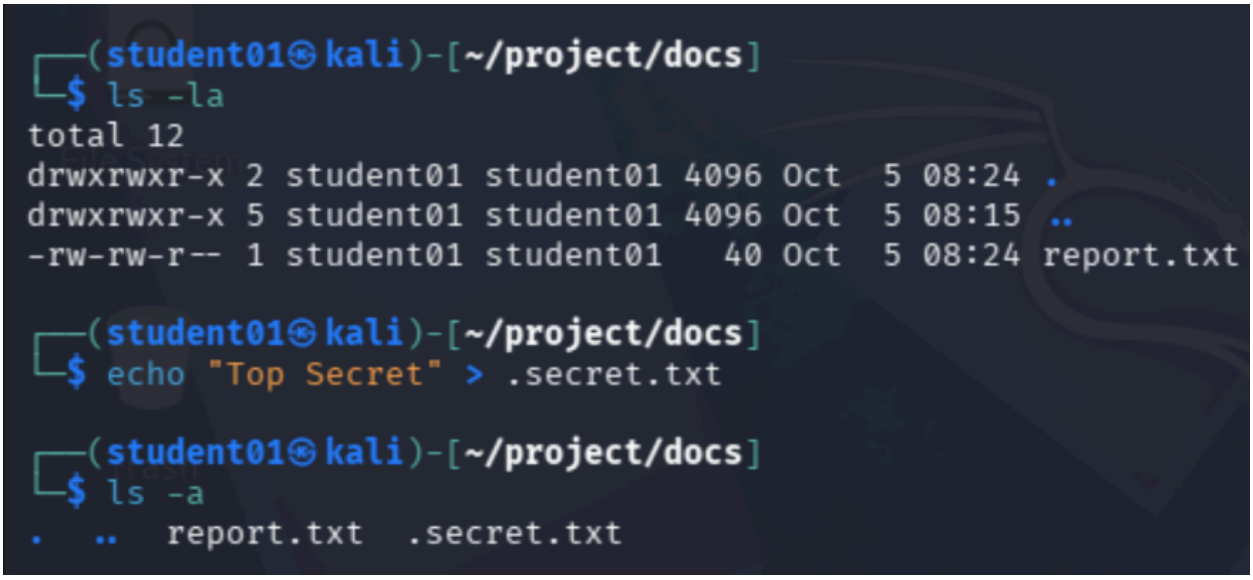

## STEP 2: Directory & File Management

1. Inside the new user's home directory:
   - Create a directory named `project`
   - Inside `project`, create the following subdirectories: `docs`, `scripts`, `bin`
2. Navigate to the `docs` directory:
   - Create a file named `report.txt` using the `echo` command with the content:
     `This is the initial report by student01.`
3. Use `ls -la` to view hidden files and directories.
4. Create a hidden file in `docs` named `.secret.txt` with the text `Top Secret`.

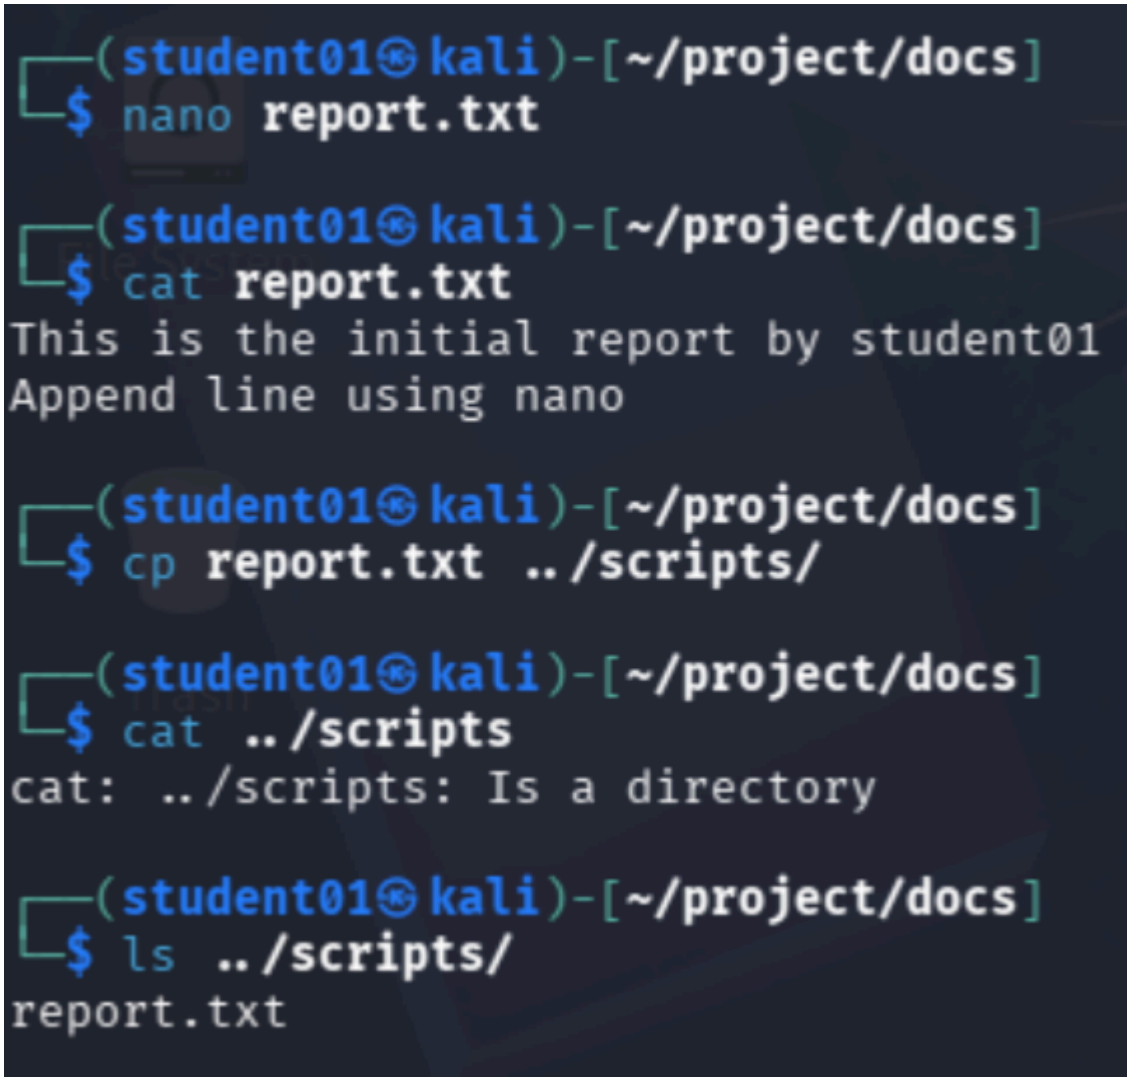

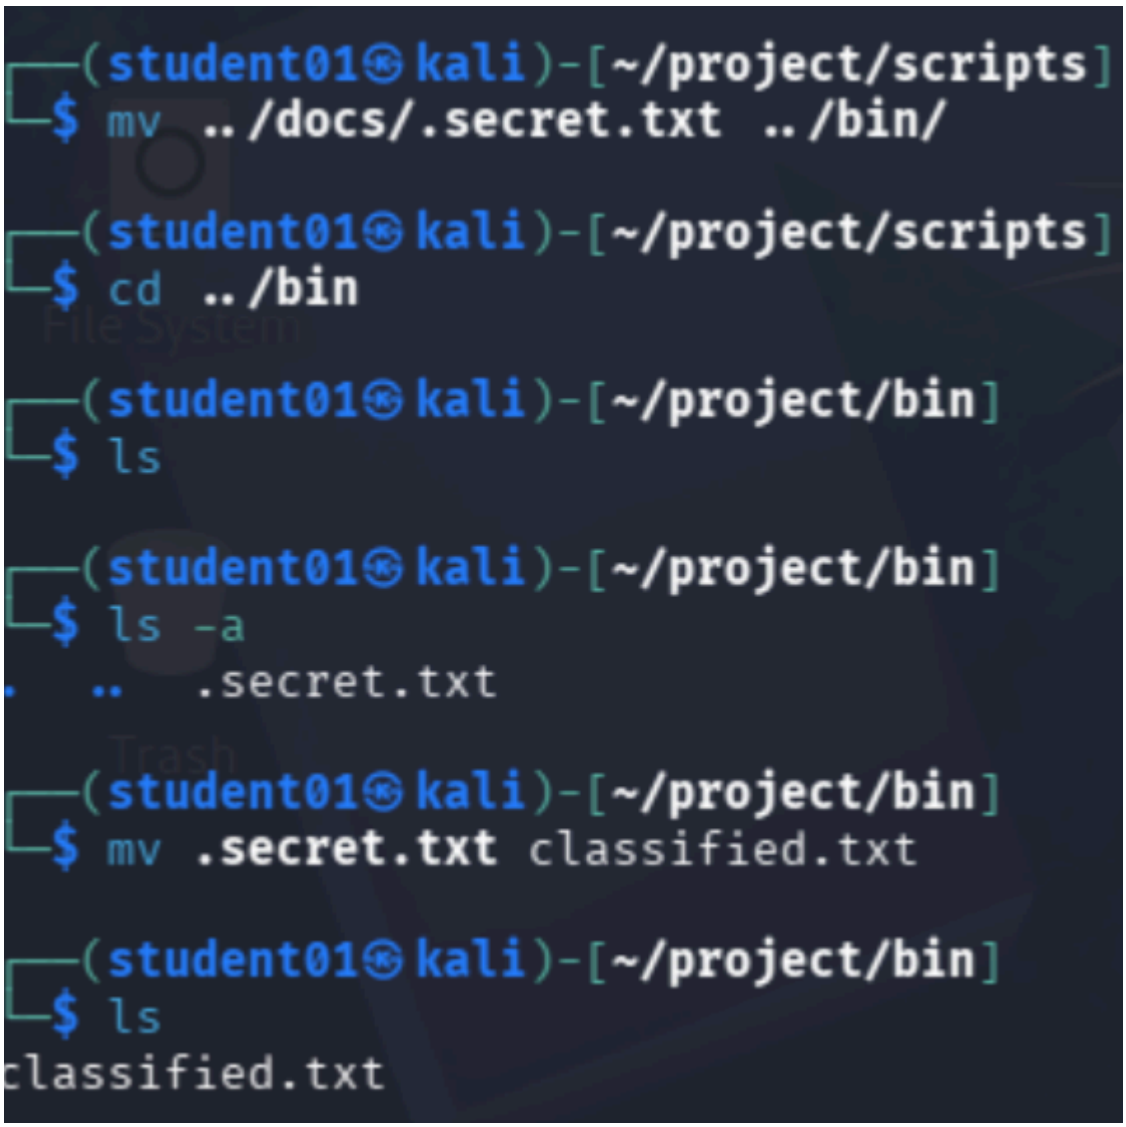

## STEP 3: Edit and Move Files

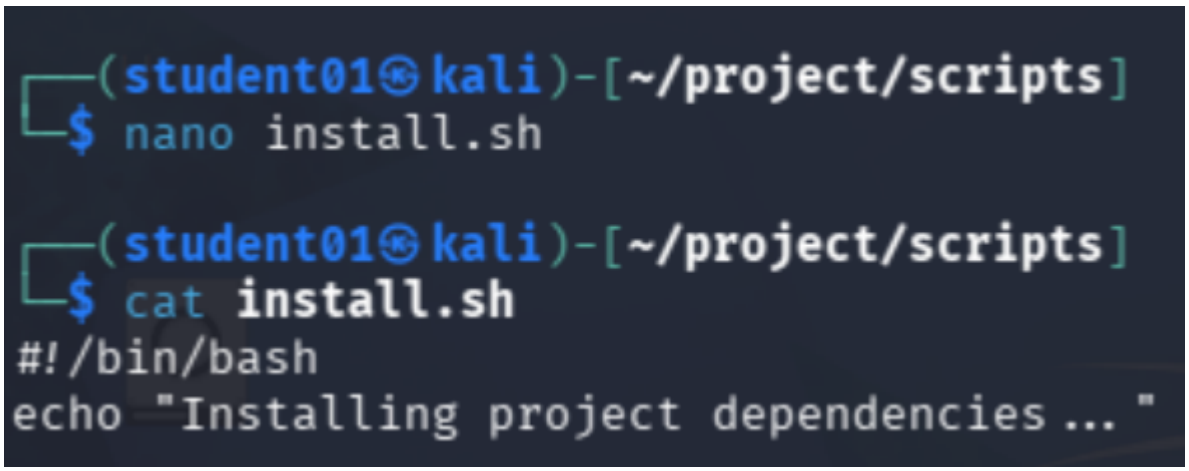

1. Open `report.txt` with `nano` and add a second line:
   `Appended line using nano.`

2. Copy `report.txt` to the `scripts` directory.
3. Move `.secret.txt` to the `bin` directory and rename it to `classified.txt` 4. Create a new file in the `scripts` directory named `install.sh` and write the following content:

```
#!/bin/bash
echo "Installing project dependencies..."
```

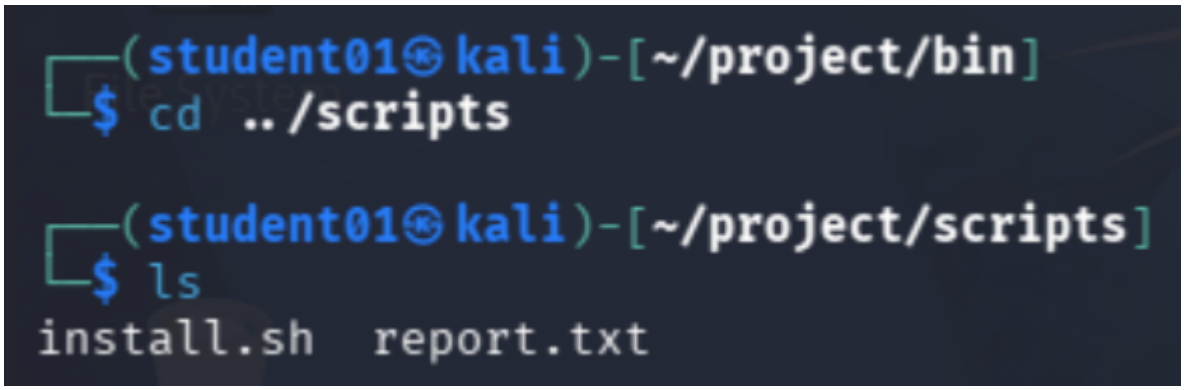

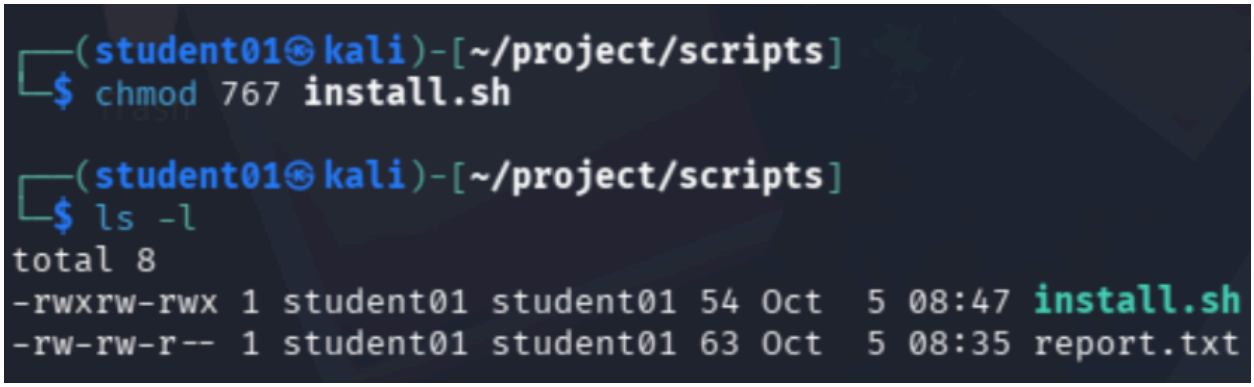

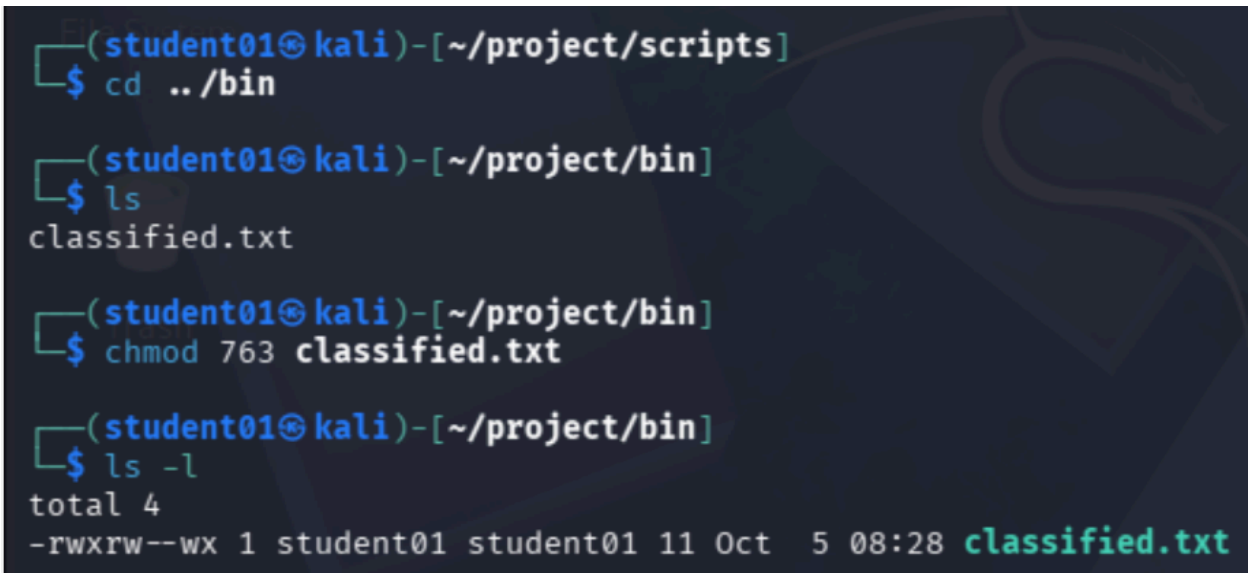

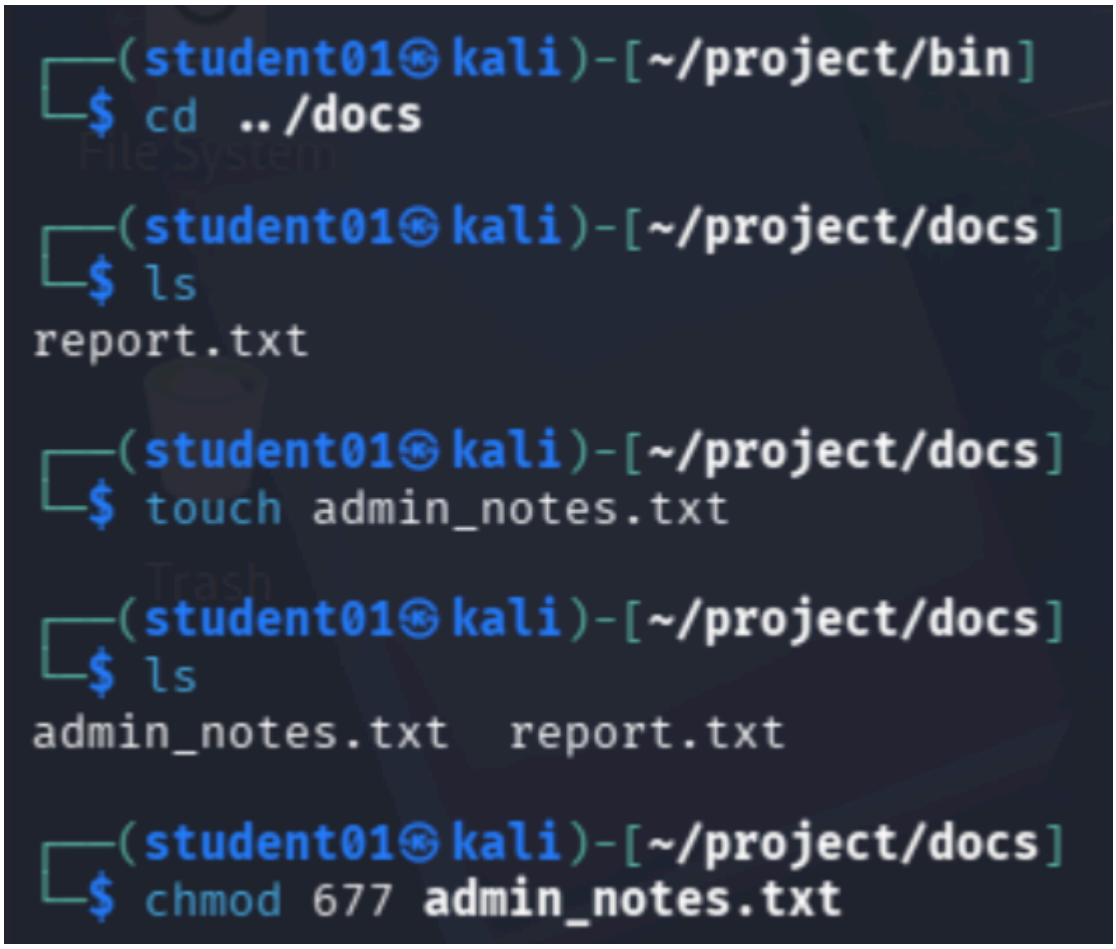

**STEP 4: Permissions with `chmod`**

1. In the `scripts` directory:
    - Make `install.sh` executable by all users.
2. In the `bin` directory:
    - Remove **read** permissions for **others** from `classified.txt`
3. In the `docs` directory:
    - Create a file named `admin_notes.txt`
    - Set the permission so that only the **owner** can read and write the file.

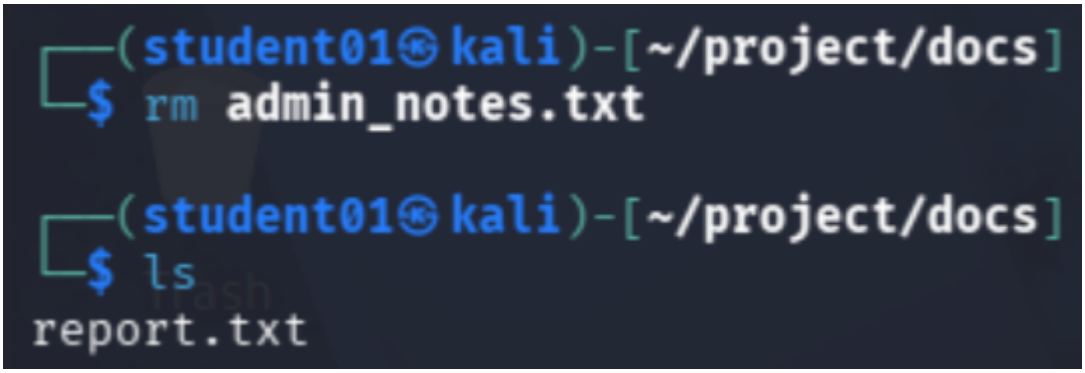

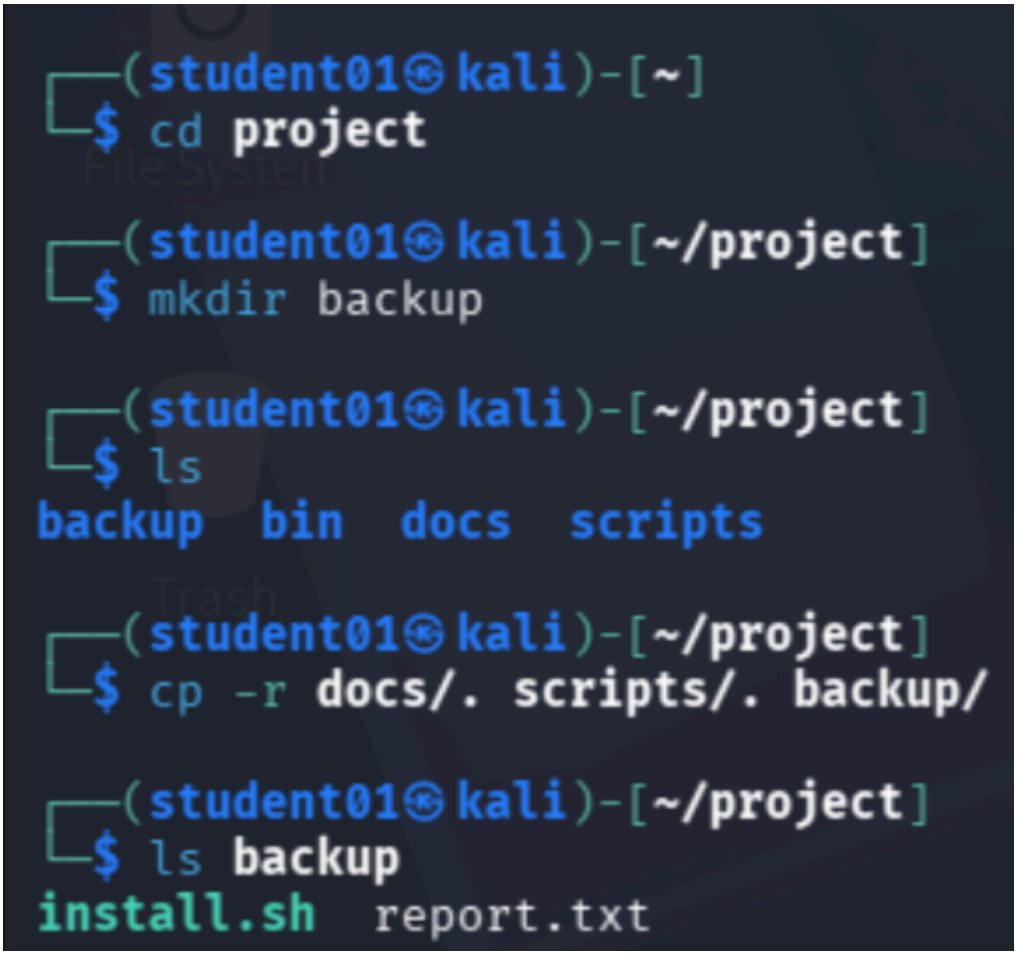

**STEP 5: Clean-Up and Final Touches**

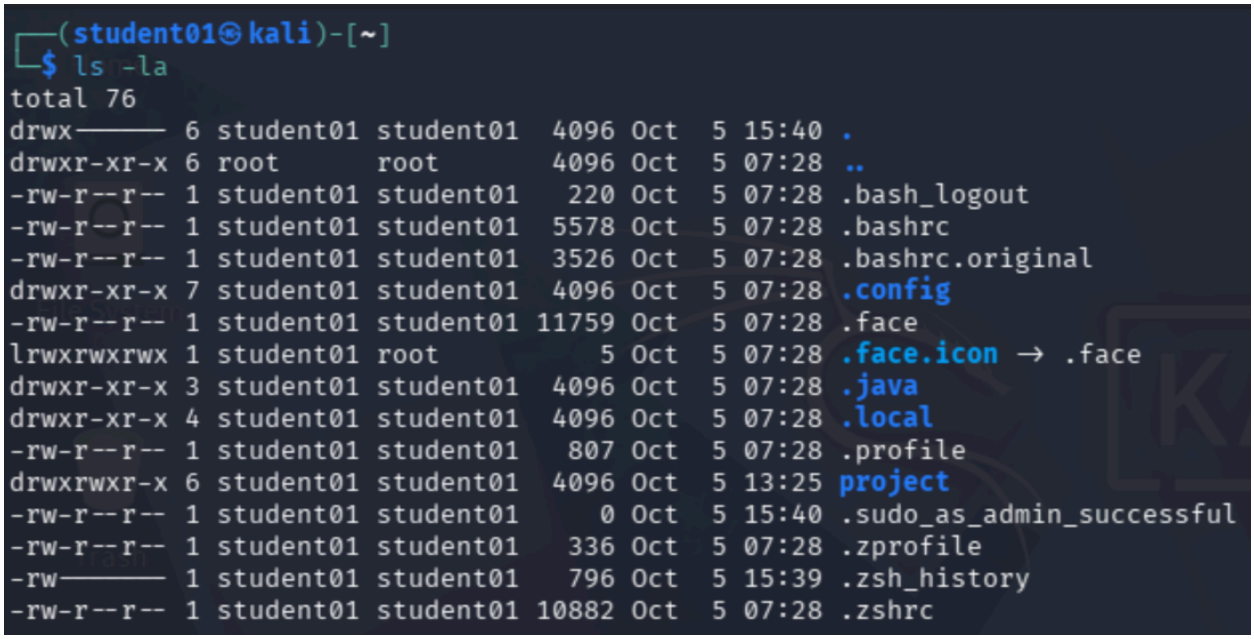

1. Delete the `admin_notes.txt` file.
2. Create a directory inside `project` called `backup`
3. Copy the entire content of `docs` and `scripts` into `backup`

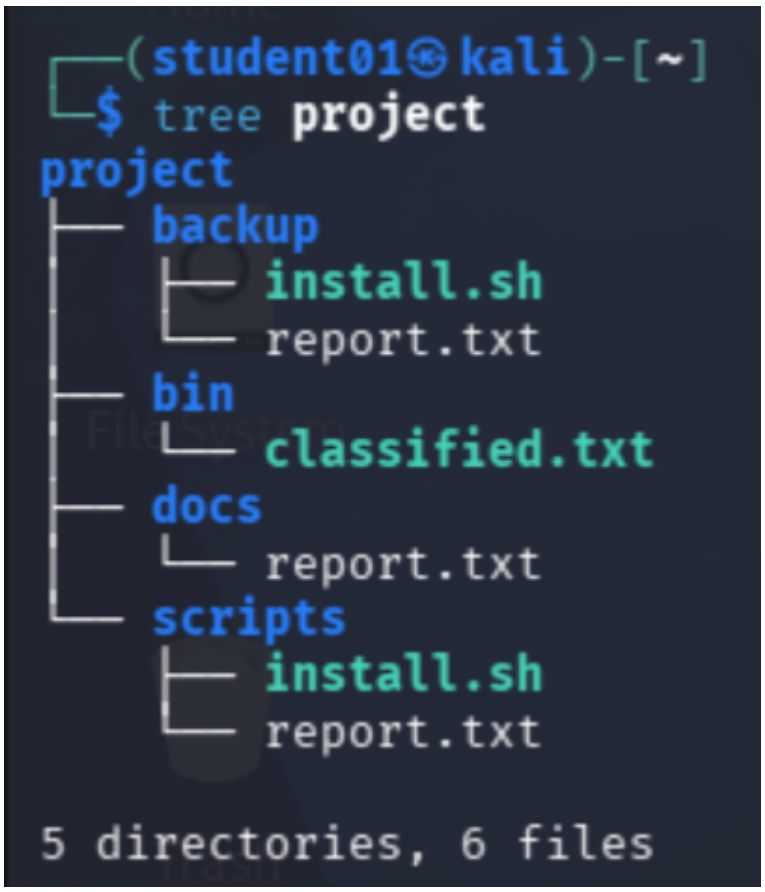

**Final Checks**

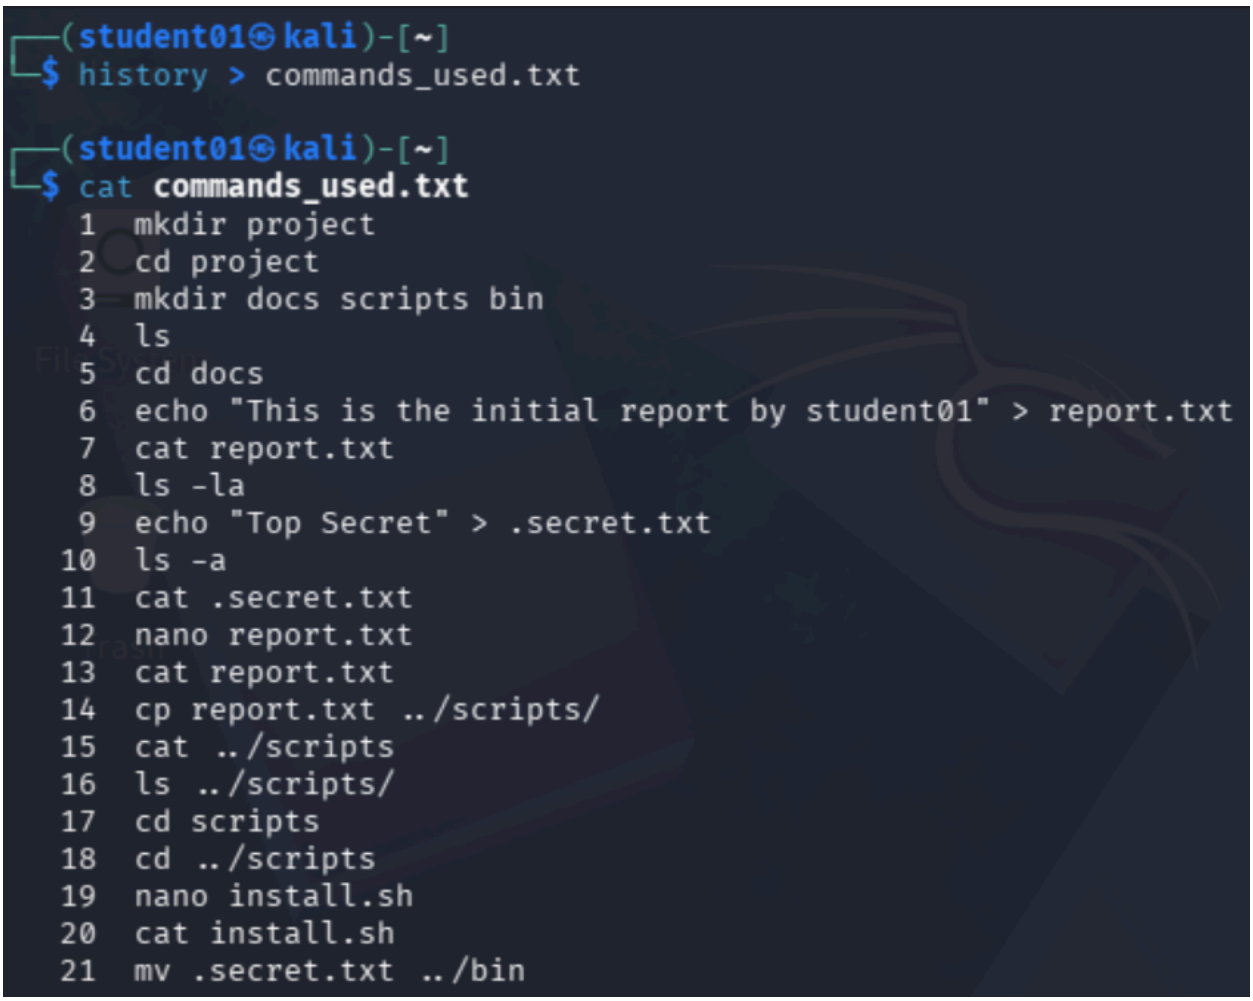

1. Navigate back to your home directory.
2. Run `tree project` (if tree isn't installed, run `sudo apt install tree` first).
3. Use `ls -la` to confirm:
    - File permissions are correctly set.
    - Files are in the correct locations.

**Bonus (Optional):**

1. Use `history` to list all commands you've run so far.
2. Redirect the history output to a file called `commands_used.txt` in your home directory using >.
